# Causal Inference in text

# Text as confounders

- Text data could either:
- (a) serve as a surrogate for potential confounders
- (b) the language of text itself could be a confounder

Example: the linguistic content of social media posts (confounder) could influence censorship (treatment) and future posting rates (outcome)

# Two similar approaches

- Topic Inverse Regression Matching
  - Roberts, Margaret E., Brandon M. Stewart, and Richard A. Nielsen. "Adjusting for confounding with text matching." *American Journal of Political Science* 64.4 (2020): 887-903.
- "Causally sufficient" embeddings
  - Veitch, Victor, Dhanya Sridhar, and David Blei. "Adapting text embeddings for causal inference." *Conference on Uncertainty in Artificial Intelligence*. PMLR, 2020.

# A different method: develop “causally sufficient” text embeddings

- Text is high dimensional and data is finite: difficult to fit models directly to text
- Instead, “reduce the text to a low-dimensional representation that suffices for causal identification and enables efficient estimation from finite data.”
- Two key ideas:
  - Supervised dimensionality reduction: we don’t need the full text, causal inference only requires the parts of text that are predictive of the treatment and outcome
  - Efficient language modeling: design representations of text to dispose of “linguistically irrelevant information”, presumed to also be “causally irrelevant”

# General approach: develop “causally sufficient” text embeddings

- Start with a neural NLP model (BERT language model) and modify it to produce 3 outputs:
  - 1) document-level embeddings
  - 2) a map from the embeddings to treatment probability
  - 3) a map from the embeddings to expected outcomes for the treated and untreated
  - [(2) and (3) are small added neural networks on the original model]
- [They also do a variant based on a topic model]

# General approach: develop “causally sufficient” text embeddings

- Train model to predict outcome, treatment, and with language-modeling objective (e.g. to learn meaningful text representations)

$$\begin{aligned} L(\mathbf{w}_i; \xi, \gamma) &= (y_i - \tilde{Q}(t_i, \lambda_i; \gamma))^2 \longrightarrow \text{Outcome} \\ &+ \text{CrossEnt}(t_i, \tilde{g}(\lambda_i; \gamma)) \longrightarrow \text{Treatment} \\ &+ L_U(\mathbf{w}_i; \xi, \gamma). \longrightarrow \text{Language modeling} \end{aligned}$$

- To compute average treatment effect, plug estimated embeddings, propensity scores, and conditional outcomes into a downstream estimator

# Evaluation

- Two settings:
  - Peer-reviewed journal articles: Causal effect of including a theorem on paper acceptance.
    - Treatment: the word “theorem” occurs in the paper
    - Confounder: article abstract (subject of the paper)
    - Outcome: accept/reject
  - Effect of gender on Reddit popularity
    - Treatment: “male” label
    - Mediator: Post text (topic or style)
    - Outcome: Popularity score

How can we use this data for *evaluation* rather than analysis?

# Evaluations

---

- Simulated data:
  - Use real confounders and treatments
  - Simulate outcomes (so we know the “true” causal effect)
- Their findings:
  - 1) Yes, language modeling helps recover simulated effects
  - 2) Yes, supervised dimensionality helps
  - 3) Their proposed models C-BERT and C-ATM outperform alternatives

# Drawing from Causal Inference to Improve NLP models

# Drawing from Causal Inference to Improve NLP models

- ML in general typically captures associates, not causal effects
- Models are prone to overfitting, exploit spurious correlations in the data
  - E.g. train a model to identify photos of dogs from cats; Model learns that dogs always have collars

→ "DOG"

# Drawing from Causal Inference to Improve NLP models

- ML in general typically captures associates, not causal effects
- Models are prone to overfitting, exploit spurious correlations in the data
  - E.g. train a model to identify photos of dogs from cats; Model learns that dogs always have collars
- Maybe by drawing from causal inference we can train models to ignore these spurious correlations, especially for tasks where it's hard to collect good training data
- Case study: drawing from causal inference to detect *subtle gender bias*

# Need to develop new models

- Our goal: detect subtle gender biases like microaggressions, objectifications, and condescension in 2nd-person text
  - “Oh, you work at an office? I bet you’re a secretary”
  - “Total tangent I know, but you’re gorgeous”
- Current classifiers that detect hate speech, offensive language, or negative sentiment cannot detect these comments
- [Note: focus on binary gender]

**Problem: Biases are *subtle, implicit, and context-dependent***

# Proposed approach: Comments contain gender bias if they are highly predictive of gender

- Train a classifier that predicts the gender of the person the text is addressed to
- If the classifier makes a prediction with high confidence, the text likely contains bias

→ Addressed to **Man**

→ Addressed to **Woman**

If a comment is very likely to be addressed to a woman, and is very unlikely to be addressed to a man, it probably contains gender bias.

# Challenge: Text main contain *confounds* that are predictive of gender, but not indicative of gender bias

I like Bob, but you're hot, so kick his butt

# A note on causal set-up

---

- We're not really doing causal inference: we are trying to build a classifier to detect microaggressions, not draw conclusions about the state of the world:
  - "confounds": spurious correlations in our data (not necessarily "confounders")
- Some of these factors that we don't want the model to learn are confounding variables

# A note on causal set-up

[Note: we have text as an outcome and as a confounder]

# Preceding context is an *observed* confounding variables

~~Saturday is the 40th anniversary of Title IX! I'm celebrating with a Sat morning run - ladies please respond below if you want to join.~~

Writer\_Gender: M

Any deal with Iran — a nation that the United States cut off diplomatic ties with 35 years ago — must protect America's interests at home and abroad.

Writer\_Gender: F

My overriding concern is whether or not the agreement is in the national security interest of the United States. Iran must be blocked from proceeding any further towards developing a nuclear weapon.

$$|e_i - e_l| \geq c \forall l$$

$$e_i = P(W.Gender_i = F | Post_i) \approx 0.91$$

$$e_j = P(W.Gender_j = F | Post_j) \approx 0.33$$

$$e_k = P(W.Gender_k = F | Post_k) \approx 0.32$$

$$\operatorname{argmin}_j |e_k - e_j|$$

# Propensity matching for *observed* confounding variables

Propensity matching breaks associations between gender and context in the training data

# Proposed Model: Comments contain bias if they are highly predictive of gender *despite confound control*

- **Substitute overt indicators**
- **Balance observed confounders through propensity matching**
- **Demote latent confounders through adversarial training**

# Self-reported microaggressions

	Public Figs		Politicians	
	F1	Acc.	F1	Acc.
base	61.3	57.3	48.1	64.2
+demotion	<b>62.2</b>	57.9	53.7	61.5
+match	38.9	55.9	46.9	50.7
+match+dem.	50.9	57.0	<b>56.9</b>	49.9
Random	46.0	49.8	-	-
Class Random	42.1	48.3	-	-

- Models are not trained at all for this task; they are only trained for gender-of-addressee prediction, but they still perform better than chance

# Findings: characteristics of bias against women politicians

---

- Influential words:
  - Competence and domesticity
  - 'Force', 'situation', 'spouse', 'family', 'love'
- Examples:
  - "DINO I hope another real Democrat challenges you next election"
  - "I did not vote for you and have no clue why anyone should have. You do not belong in politics"

# Findings: characteristics of bias against women

---

- Influential words:
  - Appearance and sexualization
  - 'beautiful', 'love', 'sexo'
- Examples:
  - "Total tangent I know but, you're gorgeous."
  - "I like Bob, but you're hot, so kick his butt."

# Network Metrics

[Slide thanks to Yuanhao (Colin) Liu]

3/04/25

# Introduction and Definitions

# Motivation: understand online “epidemic”

- Lies spread faster than the truth

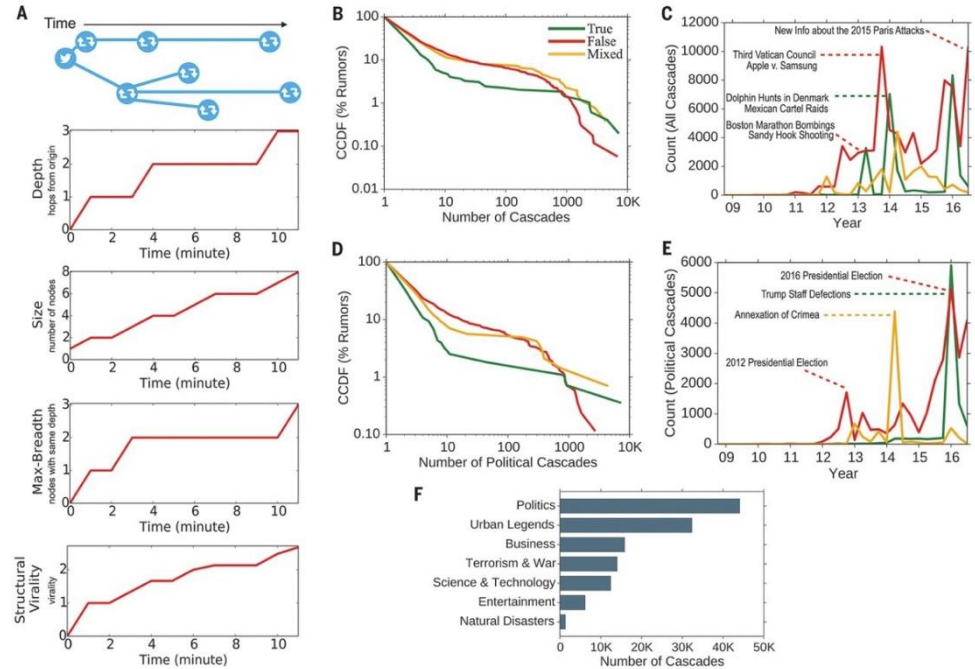

Fig. 1 Rumor cascades.

# Motivation: understand epidemic

- Sex Partner Network and HIV

Fig. 3. Size of Largest component and bicomponent by average number of sexual partners for short-tailed and scale-free distributions. The curves plot the growth of the largest component and bicomponent as a function of the average degree, based on 100 simulations of a 10,000-node network at each degree setting. The red curve plots the analytic solution for the size of the giant component for the simulated networks with scale-free distributions, and the orange curve plots the largest bicomponent. The dark blue curve plots the analytic solution for the size of the largest component for the simulated low-degree networks, and the light blue curve plots the size of the largest bicomponent. The bicomponent curves are not continuous due to sampling.

# Motivation: how to succeed as individual

- Looking for a job? Making Weak Ties.
- Want to be influential? Try something new, but don't go too far.

## The Strength of Weak Ties<sup>1</sup>

Mark S. Granovetter  
*Johns Hopkins University*

Analysis of social networks is suggested as a tool for linking micro and macro levels of sociological theory. The procedure is illustrated by elaboration of the macro implications of one aspect of small-scale interaction: the strength of dyadic ties. It is argued that the degree of overlap of two individuals' friendship networks varies directly with the strength of their tie to one another. The impact of this principle on diffusion of influence and information, mobility opportunity, and community organization is explored. Stress is laid on the cohesive power of weak ties. Most network models deal, implicitly, with strong ties, thus confining their applicability to small, well-defined groups. Emphasis on weak ties lends itself to discussion of relations *between* groups and to analysis of segments of social structure not easily defined in terms of primary groups.

## Atypical Combinations and Scientific Impact

Brian Uzzi,<sup>1,2</sup> Satyam Mukherjee,<sup>1,2</sup> Michael Stringer,<sup>2,3</sup> Ben Jones<sup>1,4\*</sup>

Novelty is an essential feature of creative ideas, yet the building blocks of new ideas are often embodied in existing knowledge. From this perspective, balancing atypical knowledge with conventional knowledge may be critical to the link between innovativeness and impact. Our analysis of 17.9 million papers spanning all scientific fields suggests that science follows a nearly universal pattern: The highest-impact science is primarily grounded in exceptionally conventional combinations of prior work yet simultaneously features an intrusion of unusual combinations. Papers of this type were twice as likely to be highly cited works. Novel combinations of prior work are rare, yet teams are 37.7% more likely than solo authors to insert novel combinations into familiar knowledge domains.

# How might we represent network?

Represent connections between vertices/nodes

- Vertex: a node of the graph
- Edge: a link between two vertices

A graph consists of a set of nodes and a set of edges

- $G(V, E)$

# Graph Data: Adjacency Matrix

- The matrix of vertices connections

Encode in a symmetric matrix (for undirected network)

$(n \times n)$  matrix  $A$

$$A = \begin{pmatrix} 0 & 1 & 1 & 1 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 \end{pmatrix}$$

The adjacency matrix has elements

$$a_{ij} = \begin{cases} 1 & \text{if } i \text{ and } j \text{ are connected} \\ 0 & \text{otherwise} \end{cases}$$

# Analyzing Networks

# Basic Metrics

- We can calculate many metrics directly from the network structure
- Example: Network density
  - Network density:  $\frac{\text{Number of edges}}{\text{Number of possible edges}}$
  - For a directed unweighted network with  $n$  nodes, the max number of possible edges is:  $n(n - 1)$

# Americans are becoming more isolated

**Table 3.** Structural Characteristics of Core Discussion Networks

	1985 (N = 1,167 <sup>a</sup> )	2004 (N = 788 <sup>b</sup> )
Network Density		
<.25	9.9%	7.3%
.25-.49	18.5%	11.8%
.50-.74	37.9%	39.5%

# Advanced analysis tasks: ERGM

- If we want to study a question like, do people share misinformation more with friends than family?
  - We define a graph where nodes are people and edges indicates misinformation sharing
  - E.g., predict will there be an edge between two family members? Does homophily drive the graph structure, e.g. edges between similar nodes?
  - We could build a prediction model like logistic regression, where we try to predict an edge given the rest of the network structure, but network features are not independent!
- One solution: Exponential Random Graph Model (ERGM)
  - Assigns  $P(Y = y) \propto \exp(\theta^T s(y))$ , where  $s(y)$  are chosen network statistics (edges, triangles, homophily, etc.) and  $Y$  is the graph we observe
  - $\theta$  are parameters we learn, e.g. through MCMC
  - We can interpret  $\theta$  directly or use it for simulations

# Advanced analysis tasks: Graph Neural Networks

- Problem: ERGM is inefficient for large dense graphs
- Solutions:
  - 1: **Network sampling.**
  - 2: **Transform** graph information to other data structures (e.g., vector - node embedding).
  - 3: Analyzing the graph at the local neural level and then aggregating the neurons together (e.g., **Graph Neural Network (GNN)**).
    - We can use GNNs for graph-level, node-level, or edge-level prediction tasks

# Recap

---

- Drawing from causal inference to improve NLP models
  - Applying ideas from causal inference to model development
- Network analysis:
  - Motivation: why do we need network analysis methods?
  - Ways to represent networks
  - Example analysis: basic metrics, ERGM, GNN
